## Estimate how much energy input by heating was transferred into the nitrogen.

## Phase change liquid to vapor (constant volume)

Neglect air in containerfor energy calculations
Mostly vapor by volume
Mostly liquid by mass

$$
\begin{aligned}
& \text { Temperature }=77 \mathrm{~K} \\
& \text { Pressure }=1 \mathrm{~atm} \\
& \text { Volume }=2 \mathrm{~L}
\end{aligned}
$$

Mass of 50 ml of liquid nitrogen

$$
\mathrm{m}=\rho \mathrm{V}=(0.808 \mathrm{~g} / \mathrm{ml})(50 \mathrm{ml})=40.4 \text { grams }
$$

*Energy input by heating

$$
\mathrm{Q}_{1}=\mathrm{mL}_{\mathrm{v}}=(40.4 \mathrm{~g})(199 \mathrm{~J} / \mathrm{g})=8040 \mathrm{~J}
$$

## Heating nitrogen vapor to $300 \mathrm{~K}\left(80^{\circ} \mathrm{F}\right)$

Temperature $=$ T, assume about 77K
Pressure = P
Volume $=2 \mathrm{~L}$

Temperature $=300 \mathrm{~K}$
Pressure increases
Volume $=2 \mathrm{~L}+$ a little (container expands)
*Energy input by heating (constant volume)

$$
\mathrm{Q}_{2}=\mathrm{mc}_{\mathrm{v}} \Delta \mathrm{~T}=(40.4 \mathrm{~g})(0.743 \mathrm{~J} / \mathrm{gK})(300 \mathrm{~K}-77 \mathrm{~K})=6700 \mathrm{~J}
$$

## Estimate for total amount of energy input by heating $\mathrm{Q}=\mathrm{Q}_{1}+\mathrm{Q}_{2}=14,740 \mathrm{~J}$

About 15,000 J
*Approximations where made to simplify the calculations. The phase change did not occur under constant temperature or pressure. The heating of the nitrogen vapor starts at a higher temperature then 77 K . Also the specificheat at constant volume changes a bit with temperature The air in the contain was not considered in these energy calculations. Even with these approximations, I think the result of several thousand Joules is a good estimate.
